Suggestion: The game class uses pieces as objects, and will be destroyed when game object ends. To better capture this relationship a stronger from of association is better suited, possibly composition or aggregation.

Feedback: Since there are various different games that require the same features such as start game, take turn, and reset game, Game class should be abstract. By making the class abstract, other games can extend the class and tailor to their personal logic while keeping the functionality the same.

Overall Feedback:While each arrow has its corresponding relationship symbol, however adding the actual relationship helps to clear up any formatting differences. This can be applicable to arrows that do not use the default UML format and helps with the overall readability of the diagram, especially when multiple classes are interacting with one another.

Additionally, it is useful to both the reader and the programmer to see the input arguments and return types for each method/constructor. When multiple classes are interacting with one another, it should show how these classes relate. For example, if object A collects object B (aggregation) then it must show object B in the field. This improves readability as well as show the boundaries of the relationship.

Feedback: Unclear how types of pieces are assigned, it would be ideal to use piece as an abstract class where there can be class that extend this class for each game. Additionally, enumeration can be used here where the piece constructor takes in an enum and sets its type.

Suggestion: checkWinCondition() and checkTieCondition() can be moved to GameLogic class where it is more appropriate. Rather than each game having different WinCondition(), it is better suit to have extensions of GameLogic since game for the most part are similar, however logic is different.

Feedback: Unclear how multiple players will interact with the board, the diagram only shows a single player interaction. May use queues along with sequence assigning to ensure each player gets their turn. Ideally this would have one to many relationship with the game since multiple players are active during game play.

Suggestion: The game class uses pieces as objects, and will be destroyed when game object ends. To better capture this relationship a stronger from of association is better suited, possibly composition or aggregation.
